Chapter 1 pointed out that hitting children is legal in every state of the United States and that 84 percent of a survey of Americans agreed that it is sometimes necessary to give a child a good hard spanking. Chapter 2 noted that almost all parents of toddlers act on these beliefs. Study after study shows that almost 100 percent of parents with toddlers hit their children. There are many reasons for the strong support of spanking. Most of them are myths.

Myth 1: Spanking Works Better

There has been a huge amount of research on the effectiveness of corporal punishment of animals, but remarkably little on the effectiveness of spanning children. That may be because almost no one, including psychologists, feels a need to study it because it is assumed that spanking is effective. In fact, what little research there is on the effectiveness of corporal punishment of children agrees with the research on animals. Studies of both animals and children show that punishment is not more effective than other methods of teaching and controlling behavior. Some studies show it is less effective.

Ellen Cohn and I asked 270 students at two New England colleges to tell us about the year they experienced the most corporal punishment. Their average age that year was eight, and they recalled having been hit an average of six times that year. We also
asked them about the percent of the time they thought that the corporal punishment was effective. It averaged a little more than half of the times (53 percent). Of course, 53 percent also means that corporal punishment was not perceived as effective about half the time it was used.

LaVoie (1974) compared the use of a loud noise (in place of corporal punishment) with withdrawal of affection and verbal explanation in a study of first- and second-grade children. He wanted to find out which was more effective in getting the children to stop touching certain prohibited toys. Although the loud noise was more effective initially, there was no difference over a longer period of time. Just explaining was as effective as the other methods.

A problem with LaVoie’s study is that it used a loud noise rather than actual corporal punishment. That problem does not apply to an experiment by Day and Roberts (1983). They studied three-year-old children who had been given “time out” (sitting in a corner). Half of the mothers were assigned to use spanking as the mode of correction if their child did not comply and left the corner. The other half put their non-complying child behind a low plywood barrier and physically enforced the child staying there. Keeping the child behind the barrier was just as effective as thespanking in correcting the misbehavior that led to the time out.

A study by Larzelere (in press) also found that a combination of non-corporal punishment and reasoning was as effective as corporal punishment and reasoning in correcting disobedience.

Crozier and Katz (1979), Patterson (1982), and Webster-Stratton et al. (1988, 1990) all studied children with serious conduct problems. Part of the treatment used in all three experiments was to get parents to stop spanking. In all three, the behavior of the children improved after spanking ended. Of course, many other things in addition to no spanking were part of the intervention. But, as you will see, parents who on their own accord do not spank also do many other things to manage their children’s behavior. It is these other things, such as setting clear standards for what is expected, providing lots of love and affection, explaining things to the child, and recognizing and rewarding good behavior, that account for why children of non-spanking parents tend to be easy to manage and well-behaved. What about parents who do these
things and also spank? Their children also tend to be well-behaved, but it is illogical to attribute that to spanking since the same or better results are achieved without spanking, and also without adverse side effects.

Such experiments are extremely important, but more experiments are needed to really understand what is going on when parents spank. Still, what Day and Roberts found can be observed in almost any household. Let's look at two examples.

In a typical American family there are many instances when a parent might say, "Mary! You did that again! I'm going to have to send you to your room again." This is just one example of a non-spanking method that did not work.

The second example is similar: A parent might say, "Mary! You did that again! I'm going to have to spank you again." This is an example of spanking that did not work.

The difference between these two examples is that when spanking does not work, parents tend to forget the incident because it contradicts the almost-universal American belief that spanking is something that works when all else fails. On the other hand, they tend to remember when a non-spanking method did not work. The reality is that nothing works all the time with a toddler. Parents think that spanking is a magic charm that will cure the child's misbehavior. It is not. There is no magic charm. It takes many interactions and many repetitions to bring up children. Some things work better with some children than with others.

Parents who favor spanking can turn this around and ask, If spanking doesn't work any better, isn't that the same as saying that it works just as well? So what's wrong with a quick slap on the wrist or bottom? There are at least three things that are wrong:

- Spanking becomes less and less effective over time and when children get bigger, it becomes difficult or impossible.
- For some children, the lessons learned through spanking include the idea that they only need to be good if Mommy or Daddy is watching or will know about it.
- As the preceding chapters show, there are a number of very harmful side effects, such as a greater chance that the child will grow up to be depressed or violent. Parents don't perceive these side effects because they usually show up only in the long run.
Myth 2: Spanking Is Needed as a Last Resort

Even parents and social scientists who are opposed to spanking tend to think that it may be needed when all else fails. There is no scientific evidence supporting this belief, however. It is a myth that grows out of our cultural and psychological commitment to corporal punishment. You can prove this to yourself by a simple exercise with two other people. Each of the three should, in turn, think of the most extreme situation where spanking is necessary. The other two should try to think of alternatives. Experience has shown that it is very difficult to come up with a situation for which the alternatives are not as good as spanking. In fact, they are usually better.

Take the example of a child running out into the street. Almost everyone thinks that spanking is appropriate then because of the extreme danger. Although spanking in that situation may help parents relieve their own tension and anxiety, it is not necessary or appropriate for teaching the child. It is not necessary because spanking does not work better than other methods, and it is not appropriate because of the harmful side effects of spanking. The only physical force needed is to pick up the child and get him or her out of danger, and, while hugging the child, explain the danger.

Ironically, if spanking is to be done at all, the “last resort” may be the worst. The problem is that parents are usually very angry by that time and act impulsively. Because of their anger, if the child rebels and calls the parent a name or kicks the parent, the episode can escalate into physical abuse. Indeed, most episodes of physical abuse started as physical punishment and got out of hand (see Chapter 5, and Kadushin and Martin, 1981). Of course, the reverse is not true, that is, most instances ofspanking do not escalate into abuse. Still, the danger of abuse is there, and so is the risk of psychological harm.

The second problem with spanking as a last resort is that, in addition to teaching that hitting is the way to correct wrongs, hitting a child impulsively teaches another incorrect lesson—that being extremely angry justifies hitting.

Myth 3: Spanking Is Harmless

When someone says, I was spanked and I’m OK, he or she is arguing that spanking does no harm. This is contrary to almost all the
available research. One reason the harmful effects are ignored is because many of us (including those of us who are social scientists) are reluctant to admit that their own parents did something wrong and even more reluctant to admit that we have been doing something wrong with our own children. But the most important reason may be that it is difficult to see the harm. Most of the harmful effects do not become visible right away, often not for years. In addition, only a relatively small percentage of spanked children experience obviously harmful effects.

The delayed reaction and the small proportion seriously hurt are the same reasons the harmful effects of smoking were not perceived for so long. In the case of smoking, the research shows that a third of very heavy smokers die of lung cancer or some other smoking-induced disease. That, of course, means that two-thirds of heavy smokers do not die of these diseases (Mattson et al., 1987). So most heavy smokers can say, I’ve smoked more than a pack a day for 30 years and I’m OK. Similarly, most people who were spanked can say, My parents spanked me, and I’m not a wife beater or depressed.

Another argument in defense of spanking is that it is not harmful if the parents are loving and explain why they are spanking. The research does show that the harmful effects of spanking are reduced if it is done by loving parents who explain their actions. However, chapters 8 and 9 and a study by Larzelere (1986) show that although the harmful effects are reduced, they are not eliminated. The chapters in Part II have shown that the harmful side effects include an increased risk of delinquency as a child and crime as an adult, wife beating, depression, masochistic sex, and lowered earnings.

In addition to having harmful psychological effects on children, hitting children also makes life more difficult for parents. Hitting a child to stop misbehavior may be the easy way in the short run, but in the slightly longer run, it makes the job of being a parent more difficult. This is because spanking reduces the ability of parents to influence their children, especially in adolescence when they are too big to control by physical force. Children are more likely to do what the parents want if there is a strong bond of affection with the parent. In short, being able to influence a child depends in considerable part on the bond between parent and child (Hirschi, 1969). An experiment by Redd, Morris, and Martin (1975) shows that
CHART 10–1. Few children of parents who use a lot of corporal punishment have a well-developed conscience.

children tend to avoid caretaking adults who use punishment. In the natural setting, of course, there are many things that tie children to their parents. I suggest that each spanking chips away at the bond between parent and child.

Part of the process by which corporal punishment eats away at the parent-child bond is shown in the study of 270 students mentioned earlier. We asked the students for their reactions to “the first time you can remember being hit by one of your parents” and the most recent instance. We used a check list of 33 items, one of which was “hated him or her.” That item was checked by 42 percent for both the first and the most recent instance of corporal punishment they could remember. The large percentage who hated their parents for hitting them is important because it is evidence
that corporal punishment does chip away at the bond between child and parent.

Contrary to the "spoiled child" myth, children of non-spanking parents are likely to be easier to manage and better behaved than the children of parents who spank. This is partly because they tend to control their own behavior on the basis of what their own conscience tells them is right and wrong rather than to avoid being hit (see Chart 10–1). This is ironic because almost everyone thinks that spanking "when necessary" makes for better behavior.

**Myth 4: One or Two Times Won't Cause Any Damage**

The evidence in this book indicates that the greatest risk of harmful effects occurs when spanking is very frequent. However, that does not necessarily mean that spanking just once or twice is harmless. Unfortunately, the connection between spanking once or twice and psychological damage has not been addressed by most of the available research. This is because the studies seem to be based on this myth. They generally cluster children into "low" and "high" groups in terms of the frequency they were hit. This prevents the "once or twice is harmless" myth from being tested scientifically because the low group may include parents who spank once a year or as often as once a month. The few studies that did classify children according to the number of times they were hit by their parents are illustrated in chapters 5, 6, and 7. They show that even one or two instances of corporal punishment are associated with a slightly higher probability of later physically abusing your own child, slightly more depressive symptoms, and a greater probability of violence and other crime later in life. The increase in these harmful side effects when parents use only moderate corporal punishment (hit only occasionally) may be small, but why run even that small risk when the evidence shows that corporal punishment is no more effective than other forms of discipline in the short run, and less effective in the long run.

**Myth 5: Parents Can’t Stop Without Training**

Although everyone can use additional skills in child management, there is no evidence that it takes some extraordinary training to be able to stop spanking. The most basic step in eliminating corporal
punishment is for parent educators, psychologists, and pediatricians to make a simple and unambiguous statement that hitting a child is wrong and that a child never, ever, under any circumstances except literal physical self-defense, should be hit.

That idea has been rejected almost without exception everytime I suggest it to parent educators or social scientists. They believe it would turn off parents and it could even be harmful because parents don’t know what else to do. I think that belief is an unconscious defense of corporal punishment. I say that because I have never heard a parent educator say that before we can tell parents to never verbally attack a child, parents need training in alternatives. Some do need training, but everyone agrees that parents who use psychological pain as a method of discipline, such as insulting or demeaning, the child, should stop immediately. But when it comes to causing physical pain by spanking, all but a small minority of parent educators say that before parents are told to stop spanking, they need to learn alternative modes of discipline. I believe they should come right out, as they do for verbal attacks, and say without qualification that a child should never be hit.

This is not to say that parent education programs are unnecessary, just that they should not be a precondition for ending corporal punishment. Most parents can benefit from parent education programs such as The Nurturing Program (Bavolek, 1983 to 1992), STEP (Dinkmeyer and McKay, 1989), Parent Effectiveness Training (Gordon, 1975), Effective Black Parenting (Alvy and Marigna, 1987), and Los Ninos Bien Educado Program (Tannatt and Alvy, 1989). However, even without such programs, most parents already use a wide range of non-spanking methods, such as explaining, reasoning, and rewarding. The problem is that they also spank. Given the fact that parents already know and use many methods of teaching and controlling, the solution is amazingly simple. In most cases, parents only need the patience to keep on doing what they were doing to correct misbehavior. Just leave out the spanking! Rather than arguing that parents need to learn certain skills before they can stop using corporal punishment, I believe that parents are more likely to use and cultivate those skills if they decide or are required to stop spanking.

This can be illustrated by looking at one situation that almost everyone thinks calls for spanking: when a toddler who runs out
into the street. A typical parent will scream in terror, rush out and
grab the child, and run to safety, telling the child, No! No! and ex-
plaining the danger—all of this accompanied by one or more slaps
to the legs or behind.

The same sequence is as effective or more effective without the
spanking. The spanking is not needed because even tiny children
can sense the terror in the parent and understand, No! No! New-
born infants can tell the difference between when a mother is re-
laxed and when she is tense (Stern, 1977). Nevertheless, the fact
that a child understands that something is wrong does not guaran-
tee never again running into the street; just as spanking does not
guarantee the child will not run into the street again.

If the child runs out again, nonspanking parents should use one of
the same strategies as spanking parents—repetition. Just as spanking
parents will spank as many times as necessary until the child learns,
parents who don’t spank should continue to monitor the child, hold
the child’s hand, and take whatever other means are needed to protect
the child until the lesson is learned. Unfortunately, when non-spank-
ing methods do not work, some parents quickly turn to spanking be-
cause they lose patience and believe it is more effective: But spanking
parents seldom question its effectiveness, they just keep on spanking.

Of course, when the child misbehaves again, most spanking par-
ents do more than just repeat the spanking or spank harder. They
usually also do things such as explain the danger to the child before
letting the child go out again or warn the child that if it happens
again, he or she will have to stay in the house for the afternoon,
and so on. The irony is that when the child finally does learn, the
parent attributes the success to the spanking, not the explanation.

Myth 6: If You Don’t Spank, Your Children
Will Be Spoiled or Run Wild

It is true that some non-spanked children run wild. But when that
happens it is not because the parent didn’t spank. It is because some
parents think the alternative to spanking is to ignore a child’s mis-
behavior or to replace spanking with verbal attacks such as, Only a
dummy like you can’t learn to keep your toys where I won’t trip
over them. The best alternative is to take firm action to correct the
misbehavior without hitting. Firmly condemning what the child has
CHART 10-2. Children of parents who use a lot of corporal punishment tend to be aggressive, especially if the parents ignore their aggression.

Done and explaining why it is wrong are usually enough. When they are not, there are a host of other things to do, such as requiring a time out or depriving the child of a privilege, neither of which involves hitting the child.

Suppose the child hits another child. Parents need to express outrage at this or the child may think it is acceptable behavior. The expression of outrage and a clear statement explaining why the child should never hit another person, except in self defense, will do the trick in most cases. That does not mean one such warning will do the trick, any more than a single spanking will do the trick. It takes most children a while to learn such things, whatever methods the parents use.
The importance of how parents go about teaching children is clear from a classic study of American parenting—*Patterns of Child Rearing* by Sears, Maccoby, and Levin (1957). This study found two actions by parents that are linked to a high level of aggression by the child: permissiveness of the child's aggression, namely ignoring it when the child hits them or another child, and spanking to correct misbehavior. The most aggressive children in Chart 10-2 are those at the upper right. They are children of parents who permitted aggression by the child and who also hit them for a variety of misbehavior. The least aggressive children are at the lower left. They are children of parents who clearly condemned acts of aggression and who, by not spanking, acted in a way that demonstrated the principle that hitting is wrong.

There are other reasons why, on the average, the children of parents who do not spank are better behaved than children of parents who spank:

- Non-spanking parents pay more attention to their children's behavior, both good and bad, than parents who spank. Consequently, they are more likely to reward good behavior and less likely to ignore misbehavior.
- Their children have fewer opportunities to get into trouble because they are more likely to child-proof the home. For older children, they have clear rules about where they can go and who they can be with.
- Non-spanking parents tend to do more explaining and reasoning. This teaches the child how to use these essential tools to monitor his or her own behavior, whereas children who are spanked get less training in thinking things through.
- Non-spanking parents treat the child in ways that tend to bond the child to them and avoid acts that weaken the bond. They tend to use more rewards for good behavior, greater warmth and affection, and fewer verbal assaults on the child (see Myth 9). By notspanking, they avoid anger and resentment over spanking. When there is a strong bond, children identify with the parent and want to avoid doing things the parent says are wrong. The child develops a conscience and lets that direct his or her behavior. That is exactly what Sears et al. found (see Chart 10-1).
Myth 7: Parents Spank Rarely or Only for Serious Problems

Contrary to this myth, parents who spank tend to use this method of discipline for almost any misbehavior. Many do not even give the child a warning. They spank before trying other things. Some advocates of spanking even recommend this. At any supermarket or other public place, you can see examples of a child doing something wrong, such as taking a can of food off the shelf. The parent then slaps the child’s hand and puts back the can, sometimes without saying a word to the child. John Rosemond, the author of *Parent Power* (1981), says, “For me, spanking is a first resort. I seldom spank, but when I decide . . . I do it, and that’s the end of it.”

The high frequency of spanking also shows up among the parents described in this book. The typical parent of a toddler told us of about 15 instances in which he or she had hit the child during the previous 12 months. That is surely a minimum estimate because spanking a child is generally such a routine and unremarkable event that most instances are forgotten. Other studies, such as Newson and Newson (1963), report much more chronic hitting of children. My tabulations for mothers of three- to five-year-old children in the National Longitudinal Study of Youth found that almost two-thirds hit their children during the week of the interview, and they did it more then three times in just that one week. As high as that figure may seem, I think that daily spanking is not at all uncommon. It has not been documented because the parents who do it usually don’t realize how often they are hitting their children.

Myth 8: By the Time a Child Is a Teenager, Parents Have Stopped

As we have seen, parents of children in their early teens are also heavy users of corporal punishment, although at that age it is more likely to be a slap on the face than on the behind. The charts in Chapter 3 show that more than half of the parents of 13 to 14-year-old children in our two national surveys hit their children in the previous 12 months. The percentage drops each year as chil-
Children get older, but even at age 17, one out of five parents is still hitting. To make matters worse, these are minimum estimates.

Of the parents of teenagers who told us about using corporal punishment, 84 percent did it more than once in the previous 12 months. For boys, the average was seven times and for girls, five times. These are minimum figures because we interviewed the mother in half the families and the father in the other half. The number of times would be greater if we had information on what the parent who was not interviewed did.

Myth 9: If Parents Don’t Spank, They will Verbally Abuse Their Child

The scientific evidence is exactly the opposite. Among the nationally representative samples of parents in this book, those who did the least spanking also engaged in the least verbal aggression.

It must be pointed out that non-spanking parents are an exceptional minority. They are defying the cultural prescription that says a good parent should spank if necessary. The depth of their involvement with their children probably results from the same underlying characteristics that led them to reject spanking. There is a danger that if more ordinary parents are told to never spank, they might replace spanking by ignoring misbehavior or by verbal attacks. Consequently, a campaign to end spanking must also stress the importance of avoiding verbal attacks as well as physical attacks, and also the importance of paying attention to misbehavior.

Myth 10: It Is Unrealistic to Expect Parents to Never Spank

It is no more unrealistic to expect parents to never hit a child than to expect that husbands should never hit their wives, or that no one should go through a stop sign, or that a supervisor should never hit an employee. Despite the legal prohibition, some husbands hit their wives, just as some drivers go through stop signs, and a supervisor occasionally may hit an employee.

If we were to prohibit spanking, as is the law in Sweden (see Chapter 11: Deley, 1988; and Haeuser, 1990), there still would be parents who would continue to spank. But that is not a reason to
avoid passing such a law here. Some people kill even though murder has been a crime since the dawn of history. Some husbands continue to hit their wives even though it has been more than a century since the courts stopped recognizing the common law right of a husband to “physically chastise an errant wife” (Calvert, 1974).

A law prohibiting spanking is unrealistic only because spanking is such an accepted part of American culture. That also was true of smoking. Yet in less than a generation we have made tremendous progress toward eliminating smoking. We can make similar progress toward eliminating spanking by showing parents that spanking is dangerous, that their children will be easier to bring up if they do not spank, and by clearly saying that a child should never, under any circumstances, be spanked.

Why Do These Myths Persist?

Some of the myths we just presented are grounded in society’s beliefs that spanking is effective and relatively harmless. Let’s turn to some of the reasons these two types of myths persist.

The Myth of Effectiveness

There are a number of reasons why almost everyone overestimates the effectiveness of spanking, but a central reason is what has been called “selective inattention.” This occurs when people do not remember the times when spanking fails because it contradicts what they believe to be true, namely, that spanking works. On the other hand if someone knows that the parents do not spank, it is assumed that the child must be spoiled or wild. So there is a tendency to overlook the good behavior of the child and to attribute the inevitable instances of misbehavior to the lack of spanking. This provides the evidence that parents who don’t spank “when necessary” have spoiled children. These all-too-human errors in information processing create the perception that spanking is much more effective than it really is. This error may be the main reason for the persistence of the effectiveness myth. The reality is that although all children misbehave, the be-
behavior of children who are not spanked, although far from perfect, is on the average better than the behavior of children whose parents spank.

The idea of selective inattention raises the question of why the “necessity” of spanking is such a deeply held belief. Why do most Americans have a vested interest in defending spanking? The following are some of the possible reasons:

- Almost all have been spanked as children, so it is part of their normal life experience.
- Even if someone is suffering from one of the harmful side effects, such as depression, he or she may not realize that having been spanked may be one of the reasons why. He or she continues to believe that spanking is harmless.
- Almost all parents slap or spank toddlers. So, if a parent accepts the idea that spanking is wrong, it implies that he or she is a bad parent, at least in this respect. That is difficult to admit.
- Almost everyone has been hit by his or her parents. So, to say corporal punishment is wrong is to condemn your own parents. Few people are comfortable doing that.
- These beliefs and attitudes have been crystallized as part of American culture and the American view of what a good parent owes a child. There is abundant evidence that people tend to misperceive things that are contrary to basic tenants of their culture and beliefs (Higgins and Bargh, 1987).
- Most spanking occurs when parents are frustrated and angry. In that context parents tend to get emotional release and satisfaction from spanking, which is confused with effectiveness in changing the child’s behavior.

There is almost always a kernel of truth behind myths and stereotypes. The belief in the usefulness of spanking is no exception. The truth is that some parents who do not spank also do not attempt to correct misbehavior. As explained earlier, children of these extremely permissive or neglectful parents do tend to be out of control. However, such parents are a minority of non-spanking parents. Their children tend to be difficult to deal with or sometimes even to be around. These few and unrepresentative cases get burned into memory.
The Myth of Harmlessness

Probably the most important reasons for the myth of harmlessness are because the harmful effects do not become visible right away, often not for years, and because only a relatively small percentage of spanked children experience obviously harmful effects.

It is now widely accepted that smoking causes lung cancer, but that fact was hotly disputed only a generation ago. The research on spanking children associates it with delinquency, wife beating, depression, and other problems later in life. But just as the research on smoking a generation ago, the evidence is not conclusive. Those favoring spanking can dismiss it, just as those favoring smoking dismissed the early inconclusive evidence.

When there is more conclusive evidence on the harmful effects of spanking, it may be harder to get people to give up spanking than it was for them to give up smoking. Spanking may be more firmly entrenched because almost everyone was spanked or is a spanker, but not everyone was a smoker.

Another reason spanking will be hard to eliminate is because the chance of falling victim to one of the harmful effects of spanking is much lower than the risk of experiencing the harmful effects of smoking. For example, Chapter 7 shows that spanked children are about four times more likely to be highly aggressive and about twice as likely to hit their spouses later in life. These are large risks, but the effects of smoking are much larger. A high rate of smoking tends to increase the chances of lung cancer by 34 times, even though two-thirds of very heavy smokers do not die of a smoking-related disease (Mattson et al., 1987).

Spanking is associated with a two-to-four-times greater rate of harmful behavior, whereas smoking increases the lung cancer rate by 34 times. Therefore, it can be argued that smoking is a much more serious problem. On the other hand, it also can be argued that spanking is the more serious problem of the two because almost all parents spank, and spanking puts entire generations at risk of harm. There is no need to decide if spanking is worse than smoking. Both are harmful, both need to be eliminated, and both can be eliminated. In the case of spanking, even though it may increase the probability of harm "only" two to four times, it is an unnecessary risk because children are more likely to be well-behaved if parents do not spank.
